

# 15. Minimum Spanning Trees

Motivation, Greedy, Algorithm Kruskal, General Rules, ADT Union-Find, Algorithm Jarnik, Prim, Dijkstra, [Ottman/Widmayer, Kap. 9.6, 6.2, 6.1, Cormen et al, Kap. 23, 19]

## Problem

*Given:* Undirected, weighted, connected graph  $G = (V, E, c)$ .

*Wanted:* Minimum Spanning Tree  $T = (V, E')$ : connected, cycle-free subgraph  $E' \subset E$ , such that  $\sum_{e \in E'} c(e)$  minimal.

381

382

## Application Examples

- Network-Design: find the cheapest / shortest network that connects all nodes.
- Approximation of a solution of the travelling salesman problem: find a round-trip, as short as possible, that visits each node once.

## Greedy Procedure

- Greedy algorithms compute the solution stepwise choosing locally optimal solutions.
- Most problems cannot be solved with a greedy algorithm.
- The Minimum Spanning Tree problem can be solved with a greedy strategy.

<sup>25</sup>The best known algorithm to solve the TS problem exactly has exponential running time.

383

384

## Greedy Idea (Kruskal, 1956)

Construct  $T$  by adding the cheapest edge that does not generate a cycle.

(Solution is not unique.)

## Algorithm MST-Kruskal( $G$ )

**Input:** Weighted Graph  $G = (V, E, c)$

**Output:** Minimum spanning tree with edges  $A$ .

Sort edges by weight  $c(e_1) \leq \dots \leq c(e_m)$

$A \leftarrow \emptyset$

**for**  $k = 1$  **to**  $|E|$  **do**

**if**  $(V, A \cup \{e_k\})$  acyclic **then**

$A \leftarrow A \cup \{e_k\}$

**return**  $(V, A, c)$

385

386

## [Correctness]

At each point in the algorithm  $(V, A)$  is a forest, a set of trees.

MST-Kruskal considers each edge  $e_k$  exactly once and either chooses or rejects  $e_k$

Notation (snapshot of the state in the running algorithm)

- $A$ : Set of selected edges
- $R$ : Set of rejected edges
- $U$ : Set of yet undecided edges

## [Cut]

A cut of  $G$  is a partition  $S, V - S$  of  $V$ . ( $S \subseteq V$ ).

An edge crosses a cut when one of its endpoints is in  $S$  and the other is in  $V \setminus S$ .

(not shown in class) 387

(not shown in class) 388

## [Rules]

- 1 Selection rule: choose a cut that is not crossed by a selected edge. Of all undecided edges that cross the cut, select the one with minimal weight.
- 2 Rejection rule: choose a circle without rejected edges. Of all undecided edges of the circle, reject those with minimal weight.

(not shown in class) 389

## [Rules]

Kruskal applies both rules:

- 1 A selected  $e_k$  connects two connection components, otherwise it would generate a circle.  $e_k$  is minimal, i.e. a cut can be chosen such that  $e_k$  crosses and  $e_k$  has minimal weight.
- 2 A rejected  $e_k$  is contained in a circle. Within the circle  $e_k$  has minimal weight.

(not shown in class) 390

## [Correctness]

### Theorem

*Every algorithm that applies the rules above in a step-wise manner until  $U = \emptyset$  is correct.*

Consequence: MST-Kruskal is correct.

(not shown in class) 391

## [Selection invariant]

**Invariant:** At each step there is a minimal spanning tree that contains all selected and none of the rejected edges.

If both rules satisfy the invariant, then the algorithm is correct.

Induction:

- At beginning:  $U = E$ ,  $R = A = \emptyset$ . Invariant obviously holds.
- Invariant is preserved at each step of the algorithm.
- At the end:  $U = \emptyset$ ,  $R \cup A = E \Rightarrow (V, A)$  is a spanning tree.

Proof of the theorem: show that both rules preserve the invariant.

(not shown in class) 392

## [Selection rule preserves the invariant]

At each step there is a minimal spanning tree  $T$  that contains all selected and none of the rejected edges.

Choose a cut that is not crossed by a selected edge. Of all undecided edges that cross the cut, select the edge  $e$  with minimal weight.

- Case 1:  $e \in T$  (done)
- Case 2:  $e \notin T$ . Then  $T \cup \{e\}$  contains a circle that contains  $e$ . Circle must have a second edge  $e'$  that also crosses the cut.<sup>26</sup> Because  $e' \notin R$ ,  $e' \in U$ . Thus  $c(e) \leq c(e')$  and  $T' = T \setminus \{e'\} \cup \{e\}$  is also a minimal spanning tree (and  $c(e) = c(e')$ ).

<sup>26</sup>Such a circle contains at least one node in  $S$  and one node in  $V \setminus S$  and therefore at least two edges between  $S$  and  $V \setminus S$ .

(not shown in class) 393

## [Rejection rule preserves the invariant]

At each step there is a minimal spanning tree  $T$  that contains all selected and none of the rejected edges.

Choose a circle without rejected edges. Of all undecided edges of the circle, reject an edge  $e$  with minimal weight.

- Case 1:  $e \notin T$  (done)
- Case 2:  $e \in T$ . Remove  $e$  from  $T$ . This yields a cut. This cut must be crossed by another edge  $e'$  of the circle. Because  $c(e') \leq c(e)$ ,  $T' = T \setminus \{e\} \cup \{e'\}$  is also minimal (and  $c(e) = c(e')$ ).

(not shown in class) 394

## Implementation Issues

Consider a set of sets  $i \equiv A_i \subset V$ . To identify cuts and circles: membership of the both ends of an edge to sets?

395

## Implementation Issues

General problem: partition (set of subsets) .e.g.  
 $\{\{1, 2, 3, 9\}, \{7, 6, 4\}, \{5, 8\}, \{10\}\}$

Required: Abstract data type “Union-Find” with the following operations

- Make-Set( $i$ ): create a new set represented by  $i$ .
- Find( $e$ ): name of the set  $i$  that contains  $e$ .
- Union( $i, j$ ): union of the sets with names  $i$  and  $j$ .

396

## Union-Find Algorithm MST-Kruskal( $G$ )

**Input:** Weighted Graph  $G = (V, E, c)$   
**Output:** Minimum spanning tree with edges  $A$ .

Sort edges by weight  $c(e_1) \leq \dots \leq c(e_m)$   
 $A \leftarrow \emptyset$   
**for**  $k = 1$  **to**  $|V|$  **do**  
     $\text{MakeSet}(k)$   
**for**  $k = 1$  **to**  $m$  **do**  
     $(u, v) \leftarrow e_k$   
    **if**  $\text{Find}(u) \neq \text{Find}(v)$  **then**  
         $\text{Union}(\text{Find}(u), \text{Find}(v))$   
         $A \leftarrow A \cup e_k$   
    **else**  
        // conceptual:  $R \leftarrow R \cup e_k$   
**return**  $(V, A, c)$

## Implementation Union-Find

Idea: tree for each subset in the partition, e.g.  
 $\{\{1, 2, 3, 9\}, \{7, 6, 4\}, \{5, 8\}, \{10\}\}$

roots = names (representatives) of the sets,  
trees = elements of the sets

397

398

## Implementation Union-Find

Representation as array:

Index	1	2	3	4	5	6	7	8	9	10
Parent	1	1	1	6	5	6	5	5	3	10

## Implementation Union-Find

Index	1	2	3	4	5	6	7	8	9	10
Parent	1	1	1	6	5	6	5	5	3	10

**Make-Set**( $i$ )     $p[i] \leftarrow i$ ; **return**  $i$

**Find**( $i$ )        **while**  $(p[i] \neq i)$  **do**  $i \leftarrow p[i]$   
                    **return**  $i$

**Union**( $i, j$ )<sup>27</sup>     $p[j] \leftarrow i$ ;

<sup>27</sup> $i$  and  $j$  need to be names (roots) of the sets. Otherwise use  $\text{Union}(\text{Find}(i), \text{Find}(j))$

399

400

## Optimisation of the runtime for Find

Tree may degenerate. Example: Union(8, 7), Union(7, 6), Union(6, 5), ...

Index	1	2	3	4	5	6	7	8	..
Parent	1	1	2	3	4	5	6	7	..

Worst-case running time of Find in  $\Theta(n)$ .

401

## Optimisation of the runtime for Find

Idea: always append smaller tree to larger tree. Requires additional size information (array)  $g$

---

**Make-Set( $i$ )**  $p[i] \leftarrow i; g[i] \leftarrow 1; \text{return } i$

---

**Union( $i, j$ )** **if**  $g[j] > g[i]$  **then**  $\text{swap}(i, j)$   
 $p[j] \leftarrow i$   
**if**  $g[i] = g[j]$  **then**  $g[i] \leftarrow g[i] + 1$

---

$\Rightarrow$  Tree depth (and worst-case running time for Find) in  $\Theta(\log n)$

402

## [Observation]

### Theorem

*The method above (union by size) preserves the following property of the trees: a tree of height  $h$  has at least  $2^h$  nodes.*

Immediate consequence: runtime Find =  $\mathcal{O}(\log n)$ .

(not shown in class) 403

## [Proof]

Induction: by assumption, sub-trees have at least  $2^{h_i}$  nodes. WLOG:  $h_2 \leq h_1$

- $h_2 < h_1$ :

$$h(T_1 \oplus T_2) = h_1 \Rightarrow g(T_1 \oplus T_2) \geq 2^{h_1}$$

- $h_2 = h_1$ :

$$g(T_1) \geq g(T_2) \geq 2^{h_2}$$

$$\Rightarrow g(T_1 \oplus T_2) = g(T_1) + g(T_2) \geq 2 \cdot 2^{h_2} = 2^{h(T_1 \oplus T_2)}$$

(not shown in class) 404

## Further improvement

Link all nodes to the root when Find is called.

Find( $i$ ):

```
 $j \leftarrow i$   
while ( $p[j] \neq i$ ) do  $i \leftarrow p[j]$   
while ( $j \neq i$ ) do  
   $t \leftarrow j$   
   $j \leftarrow p[j]$   
   $p[t] \leftarrow i$   
return  $i$ 
```

Cost: amortised *nearly* constant (inverse of the Ackermann-function).<sup>28</sup>

<sup>28</sup>We do not go into details here.

## Running time of Kruskal's Algorithm

- Sorting of the edges:  $\Theta(|E| \log |E|) = \Theta(|E| \log |V|)$ .<sup>29</sup>
  - Initialisation of the Union-Find data structure  $\Theta(|V|)$
  - $|E| \times \text{Union}(\text{Find}(x), \text{Find}(y))$ :  $\mathcal{O}(|E| \log |E|) = \mathcal{O}(|E| \log |V|)$ .
- Overall  $\Theta(|E| \log |V|)$ .

<sup>29</sup>because  $G$  is connected:  $|V| \leq |E| \leq |V|^2$

405

406

## Algorithm of Jarnik (1930), Prim, Dijkstra (1959)

Idea: start with some  $v \in V$  and grow the spanning tree from here by the acceptance rule.

```
 $A \leftarrow \emptyset$   
 $S \leftarrow \{v_0\}$   
for  $i \leftarrow 1$  to  $|V|$  do  
  Choose cheapest  $(u, v)$  mit  $u \in S, v \notin S$   
   $A \leftarrow A \cup \{(u, v)\}$   
   $S \leftarrow S \cup \{v\}$  // (Coloring)
```

Remark: a union-Find data structure is not required. It suffices to color nodes when they are added to  $S$ .

## Running time

Trivially  $\mathcal{O}(|V| \cdot |E|)$ .

Improvement (like with Dijkstra's ShortestPath)

- With Min-Heap: costs
  - Initialization (node coloring)  $\mathcal{O}(|V|)$
  - $|V| \times \text{ExtractMin} = \mathcal{O}(|V| \log |V|)$ ,
  - $|E| \times \text{Insert or DecreaseKey} = \mathcal{O}(|E| \log |V|)$ ,

$\mathcal{O}(|E| \cdot \log |V|)$

407
