What is Computer Science?

1. Introduction

Computer Science: Definition and History, Algorithms, Turing Machine, Higher Level Programming Languages, Tools, The first C++Program and its Syntactic and Semantic Ingredients

The science of systematic processing of informations,...

• ... particularly the automatic processing using digital computers.

24

26

(Wikipedia, according to "Duden Informatik")

Informatics \neq Science of Computers	Computer Science \subseteq Informatics
Computer science is not about machines, in the same way that astronomy is not about telescopes. Mike Fellows, US Computer Scientist (1991)	 Computer science is also concerned with the development of fast computers and networks but not as an end in itself but for the systematic processing of informations.

Computer Science \neq Computer Literacy

Computer literacy: user knowledge

- Handling a computer
- Working with computer programs for text processing, email, presentations . . .

Computer Science Fundamental knowledge

- How does a computer work?
- How do you write a computer program?

This course

- Systematic problem solving with algorithms and the programming language C++.
- Hence: not only but also programming course.

Algorithm: Fundamental Notion of Computer Science

Algorithm:

- Instructions to solve a problem step by step
- Execution does not require any intelligence, but precision (even computers can do it)
- according to Muhammed al-Chwarizmi, author of an arabic computation textbook (about 825)

Oldest Nontrivial Algorithm

Euclidean algorithm (from the *elements* from Euklid, 3. century B.C.)

Input: integers a > 0, b > 0Output: gcd of a und b
While $b \neq 0$ If a > b then $a \leftarrow a - b$ else:

$$b \leftarrow b - a$$

Result: a.

27

1964: Erstmals können ETH-Studierende selbst einen Computer programmieren (die CDC 1604, gebaut von Seymour Cray).

ETH: pioneer of modern computer science

Die Klasse 1964 im Jahr 2015 (mit einigen Gästen)

ETH: pioneer of modern computer science

1968–1990: Niklaus Wirth entwickelt an der ETH die Programmiersprachen Pascal, Modula-2 und Oberon und 1980 die Lilith, einen der ersten Computer mit grafischer Benutzeroberfläche.

Computers – Concept

A bright idea: universal Turing machine (Alan Turing, 1936)

Folge von Symbolen auf Ein- und Ausgabeband

چ 35

Computer – Implementation

- Z1 Konrad Zuse (1938)
- ENIAC John Von Neumann (1945)

Von Neumann Architektur

Computer

Ingredients of a Von Neumann Architecture

- Memory (RAM) for programs and data
- Processor (CPU) to process programs and data
- I/O components to communicate with the world

Memory for data and program

- Sequence of bits from $\{0, 1\}$.
- Program state: value of all bits.
- Aggregation of bits to memory cells (often: 8 Bits = 1 Byte)
- Every memory cell has an address.
- Random access: access time to the memory cell is (nearly) independent of its address.

|--|

Processor

The processor (CPU)

- executes instructions in machine language
- has an own "fast" memory (registers)
- can read from and write to main memory
- features a set of simplest operations = instructions (e.g. adding to register values)

40

Computing speed

In the time, on average, that the sound takes to travel from from my mouth to you ...

 $30 \text{ m} \cong \text{more than } 100.000.000 \text{ instructions}$

a contemporary desktop PC can process more than 100 millions instructions ²

²Uniprocessor computer at 1 GHz.

Why programming?

- Do I study computer science or what ...
- There are programs for everything ...
- I am not interested in programming ...
- because computer science is a mandatory subject here, unfortunately...
- **...**

Programming

- With a programming language we issue commands to a computer such that it does exactly what we want.
- The sequence of instructions is the (computer) program

The Harvard Computers, human computers, ca.1890

Mathematics used to be the lingua franca of the natural sciences on all universities. Today this is computer science.

Lino Guzzella, president of ETH Zurich, NZZ Online, 1.9.2017

This is why programming!

Programming Languages

- Any understanding of modern technology requires knowledge about the fundamental operating principles of a computer.
- Programming (with the computer as a tool) is evolving a cultural technique like reading and writing (using the tools paper and pencil)
- Most qualified jobs require at least elementary programming skills
- Programming is fun!

The language that the computer can understand (machine language) is very primitive.

- Simple operations have to be subdivided into many single steps
- The machine language varies between computers.

Higher Programming Languages

can be represented as program text that

- can be understood by humans
- is *independent* of the computer model
 - \rightarrow Abstraction!

Programming langauges – classification

Differentiation into

- Compiled vs. interpreted languages
 - C++, C#, Pascal, Modula, Oberon, Java vs.
 Python, Tcl, Matlab
- Higher programming languages vs. Assembler
- Multi-purpose programming languages vs. single purpose programming languages
- Procedural, object oriented, functional and logical languages.

50

Why C++?

Other popular programming languages: Java, C#, Objective-C, Modula, Oberon, Python ...

- \blacksquare C++ is practically relevant.
- For the computational computing (as required in math and physics), C++ offers a lot of useful concepts.
- C++ is widespread and "runs everywhere"
- \blacksquare C++ is standardized i.e. there is an "official" C++.
- The lecturer likes C++.

Why C++?

- C++equips C with the power of the abstraction of a higher programming language
- In this course: C++ introduced as high level language, not as better C

52

54

• Approach: traditionally procedural \rightarrow object-oriented.

Deutsch vs. C++Syntax andDeutsch
Es ist nicht genug zu wissen,
man muss auch anwenden.
(Johann Wolfgang von Goethe)• Like our lar
certain rule
• Syntax:
• SemantC++// computation
int b = a * a; // b = a^2
b = b * b; // b = a^4• Correspond
more strict

Syntax and Semantics

- Like our language, programs have to be formed according to certain rules.
 - Syntax: Connection rules for elementary symbols (characters)
 - Semantics: interpretation rules for connected symbols.
- Corresponding rules for a computer program are simpler but also more strict because computers are relatively stupid.

$\mathrm{C}{++}{:}$ Kinds of errors illustrated with German sentences

- Das Auto fuhr zu schnell.
- DasAuto fuh r zu sxhnell.
- Rot das Auto ist.
- Man empfiehlt dem Dozenten nicht zu widersprechen
- Sie ist nicht gross und rothaarig.
- Die Auto ist rot.
- Das Fahrrad gallopiert schnell.
- Manche Tiere riechen gut.

Syntax and Semantics of $\mathrm{C}{++}$

Syntax

- What *is* a C++ program?
- Is it grammatically correct?

Semantics

- What does a program mean?
- What kind of algorithm does a program implement?

56

58

Syntax and semantics of $\mathrm{C}{++}$

The ISO/IEC Standard 14822 (1998, 2011,...)

- \blacksquare is the "law" of $\mathrm{C}{++}$
- defines the grammar and meaning of C++programs
- contains new concepts for *advanced* programming ...
- ... which is why we will not go into details of such concepts

Programming Tools

- **Editor:** Program to modify, edit and store C++program texts
- Compiler: program to translate a program text into machine language
- **Computer:** machine to execute machine language programs
- Operating System: program to organize all procedures such as file handling, editor-, compiler- and program execution.

Language constructs with an example

- Comments/layout
- Include directive
- the main function
- Values effects
- Types and functionality
- literals
- variables

- constants
- identifiers, names
- objects
- expressions
- L- and R- values
- operators
- statements

The first C++ program Most important ingredients...

```
// Program: power8.cpp
// Raise a number to the eighth power.
#include <iostream>
int main() {
   // input
   std::cout << "Compute a^8 for a =? ";</pre>
   int a;
   // computation
   int b = a * a; // b = a<sup>2</sup> \leftarrow Expressions: Compute a value (a^2)!
   b = b * b; // b = a^4
   // output b * b, i.e., a<sup>8</sup>
   std::cout << a << "^8 = " << b * b << "\n";</pre>
   return 0;
```

60

62

Behavior of a Program	"Accessories:" Comments
At compile time: program accepted by the compiler (syntactically correct) Compiler error During runtime: correct result incorrect result program crashes program does not terminate (endless loop) 	<pre>// Program: power8.cpp // Raise a number to the eighth power. #include <iostream> int main() { // input (compute a^8 for a =? "; int a; std::cin >> a; // computation (computation (computation</iostream></pre>
	L L L L L L L L L L L L L L L L L L L

}

Comments and Layout

Comments

- are contained in every good program.
- document *what* and *how* a program does something and how it should be used,
- are ignored by the compiler
- Syntax: "double slash" // until the line ends.

The compiler *ignores* additionally

- Empty lines, spaces,
- Indendations that should reflect the program logic

Comments and Layout

The compiler does not care...

#include <iostream>
int main(){std::cout << "Compute a^8 for a =? ";
int a; std::cin >> a; int b = a * a; b = b * b;
std::cout << a << "^8 = " << b*b << "\n";return 0;}</pre>

64

66

... but we do!

"Accessories:" Include and Main Function	Include Directives
<pre>// Program: power8.cpp // Raise a number to the eighth power. #include <iostream></iostream></pre>	<pre>C++ consists of the core language standard library in-/output (header iostream) mathematical functions (cmath) #include <iostream> makes in- and output available</iostream></pre>

The main Function

the main-function

- is provided in any C++ program
- is called by the operating system
- like a mathematical function ...
 - arguments
 - return value
- ... but with an additional *effect*
 - Read a number and output the 8th power.

Statements: Do something!

68

70

Statements Expression Statements • building blocks of a C++ program • have the following form: • are executed (sequentially) • end with a semicolon • any statement has an effect (potentially) • the effect of expr, the value of expr is ignored. • Effect is the effect of expr, the value of expr is ignored. • Example: • = b*b;

Return Statements

do only occur in functions and are of the form

return expr;

- where *expr* is an expression
- specify the return value of a function

Example: return 0;

Statements – Effects

int main() {

Values and Effects

- determine what a program does,
- are purely semantical concepts:
 - Symbol 0 means Value $0 \in \mathbb{Z}$
 - std::cin >> a; means effect "read in a number"
- depend on the program state (memory content, inputs)

Statements – Variable Definitions

71

Declaration Statements

- introduce new names in the program,
- consist of declaration and semicolon

Example: int a;

can initialize variables

Example: int b = a * a;

Types and Functionality

int:

- C++ integer type
- corresponds to $(\mathbb{Z}, +, \times)$ in math

In $\mathrm{C}{++}$ each type has a name and

- a domain (e.g. integers)
- functionality (e.g. addition/multiplication)

76

78

Fundamental Types	Literals
$\mathrm{C}{++}$ comprises fundamental types for	represent constant values
integers (int)	have a fixed type and value
natural numbers (unsigned int)	are "syntactical values".
real numbers (float, double)	Examples:
boolean values (bool)	O has type int, value 0.
 	1.2e5 has type double, value $1.2 \cdot 10^5$.

Variables

- represent (varying) values,
- have
 - name
 - type
 - value
 - address
- are "visible" in the program context.

Beispiel

int a; defines a variable with

- name: a
- type: int
- value: (initially) undefined
- Address: determined by compiler

Objects

- represent values in main memory
- have *type*, *address* and *value* (memory content at the address)
- can be named (variable) ...
- ... but also anonymous.

Remarks

A program has a *fixed* number of variables. In order to be able to deal with a variable number of value, it requires "anonymous" addresses that can be address via temporary names.

80

82

Identifiers and NamesExpressions: compute a value!(Variable-)names are identifiers represent Computationsare either primary (b)or composed (b*b)...or composed (b*b)...... from different expressions, using operatorshave a type and a valueAnalogy: building blocks

Expressions	Building Blocks	Expressions
<pre>composite express // input std::cout << "Compute a^8 for a =? "; int a; std::cin >> a;</pre>	sion	 represent <i>computations</i> are <i>primary</i> or <i>composite</i> (by other expressions and operations)
<pre>// computation int b = a * a; // b = a^2 b = b * b Two times composed expression</pre>		a * a composed of variable name, operator symbol,variable name variable name: primary expression
<pre>// output b * b, i.e., a^8 std::cout << a<< "^8 = " << b * b << ".\</pre>	n";	 can be put into parantheses a * a is equivalent to (a * a)
	83	

Expressions

have *type*, *value* und *effect* (potentially).

Example	Example
a * a	b = b * b
type: int (type of the operands)	 type: int (Typ der Operanden)
 Value: product of a and a 	Value: product of b and b
Effect: none.	 effect: assignment of the product value to b

The type of an expression is fixed but the value and effect are only determined by the *evaluation* of the expression

L-Values and R-Values

L-Values and R-Values

- L-Wert ("Left of the assignment operator")
 - Expression with address
 - Value is the content at the memory location according to the type of the expression.
 - L-Value can change its value (e.g. via assignment)

Example: variable name

L-Values and R-Values

R-Wert ("Right of the assignment operator")

Expression that is no L-value

Example: literal 0

Any L-Value can be used as R-Value (but not the other way round)

88

An R-Value cannot change its value

Operators

Operators

- combine expressions (*operands*) into new composed expressions
- specify for the operands and the result the types and if the have to be L- or R-values.
- have an arity

Multiplication Operator *

- expects two R-values of the same type as operands (arity 2)
- "returns the product as R-value of the same type", that means formally:
 - The composite expression is an R-value; its value is the product of the value of the two operands

92

94

Examples: a * a and b * b

Assignment Operator = Input Operator >> Left operand is L-value, left operand is L-Value (input stream) Right operand is R-value of the same type. right operand is L-Value Assigns to the left operand the value of the right operand and assigns to the right operand the next value read from the input returns the left operand as L-value stream, removing it from the input stream and returns the input stream as L-value Examples: b = b * b and a = bExample std::cin >> a (mostly keyboard input) Attention, Trap! Input stream is being changed and must thus be an L-Value. The operator = corresponds to the assignment operator of mathematics (:=), not to the comparison operator (=).

Output Operator <<

- left operand is L-Value (output stream)
- right operand is R-Value
- outputs the value of the right operand, appends it to the output stream and returns the output stream as L-Value

Example: std::cout << a (mostly console output)</pre>

The output stream is being changed and must thus be an L-Value.

Output Operator <<

Why returning the output stream?

allows bundling of output

std::cout << a << "^8 = " << b * b << "\n"

is parenthesized as follows

(((((std::cout << a) << "^8 = ") << b * b) << "\n")

std::cout << a is the left hand operand of the next << and is thus an L-Value that is no variable name

96

98

power8_exact.cpp

- Problem with power8.cpp: large input values are not correctly handled
- reason: domain of the type int is limited
- solution: use a different type
 - e.g. ifm::integer

power8_exact.cpp

```
// Program: power8_exact.cpp
// Raise a number to the eighth power,
// using integers of arbitrary size
```

```
#include <iostream>
#include <IFMP/integer.h>
```

int main()
{

```
// input
std::cout << "Compute a^8 for a =? ";
ifmp::integer a;
std::cin >> a;
```

```
// output b * b, i.e., a^8
std::cout << a << "^8 = " << b * b << ".\n";
return 0;</pre>
```

}
