

## 23. Dynamic Datatypes and Memory Management

# Problem

Last week: dynamic data type

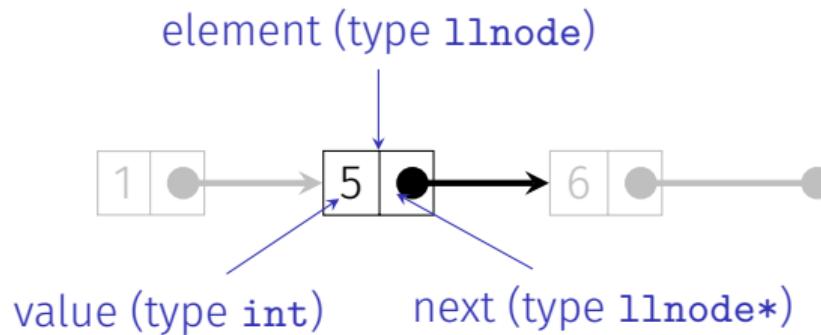

Have allocated dynamic memory, but not released it again. In particular:  
no functions to remove elements from `llvec`.

Today: correct memory management!

# Goal: class stack with memory management

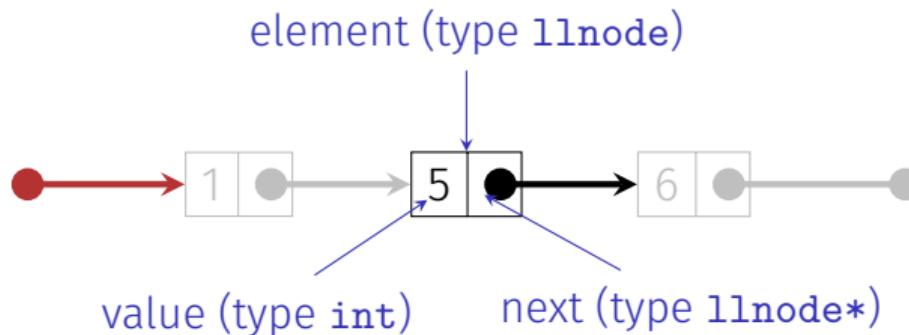

```
class stack{
public:
    // post: Push an element onto the stack
    void push(int value);
    // pre: non-empty stack
    // post: Delete top most element from the stack
    void pop();
    // pre: non-empty stack
    // post: return value of top most element
    int top() const;
    // post: return if stack is empty
    bool empty() const;
    // post: print out the stack
    void print(std::ostream& out) const;
...
}
```

# Recall the Linked List

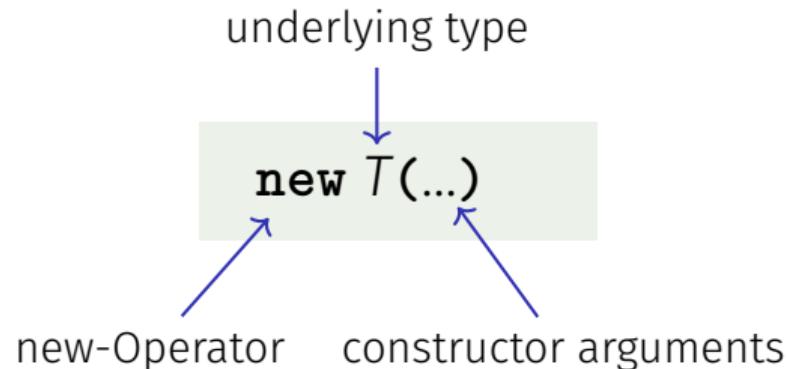

```
struct llnode {  
    int value;  
    llnode* next;  
    // constructor  
    llnode (int v, llnode* n) : value (v), next (n) {}  
};
```

# Stack = Pointer to the Top Element

```
class stack {  
public:  
    void push (int value);  
    ...  
private:  
    llnode* topn;  
};
```

# Recall the `new` Expression

- **Effect:** memory for a new object of type  $T$  is allocated ...
- ...and initialized by means of the matching constructor
- **Value:** address of the new  $T$  object, **Type:** Pointer  $T^*$ !

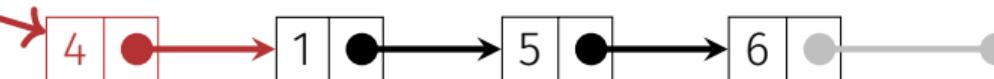

# The `new` Expression

`push(4)`

- **Effect:** new object of type  $T$  is allocated in memory ...
- ...and initialized by means of the matching constructor
- **Value:** address of the new object

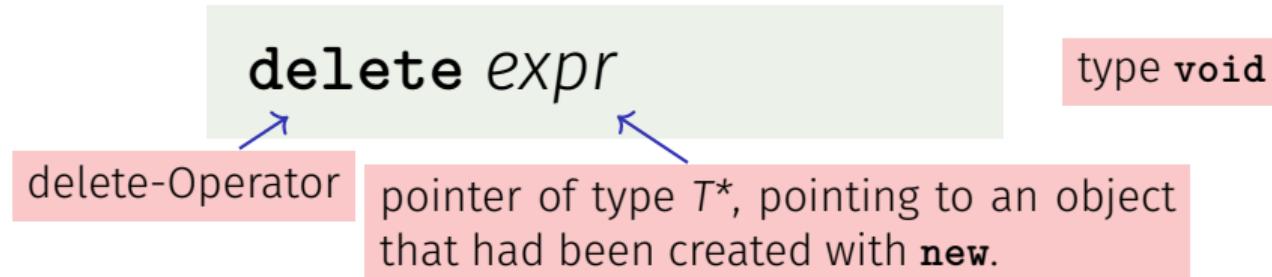

```
void stack::push(int value) {  
    topn = new llnode(value, topn);  
}
```

`topn`

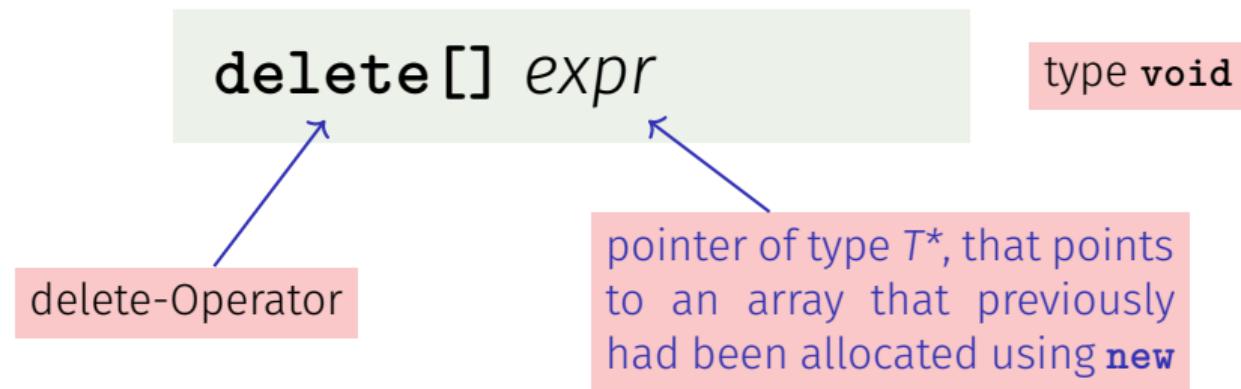

# The `delete` Expression

Objects generated with `new` have **dynamic storage duration**: they “live” until they are explicitly *deleted*

- **Effect:** object is **deconstructed** (explanation below)  
... and **memory is released**.

# delete for Arrays

- **Effect:** array is deleted and memory is released

# Who is born must die...

Guideline “Dynamic Memory”

For each `new` there is a matching `delete!`

Non-compliance leads to memory leaks

- old objects that occupy memory...
- ...until it is full (**heap overflow**)

# Careful with `new` and `delete`!

```
rational* t = new rational; ← memory for t is allocated  
rational* s = t; ← other pointers may point to the same object  
delete s; ← ... and used for releasing the object  
int nominator = (*t).denominator(); ← error: memory released!  
                                ↑
```

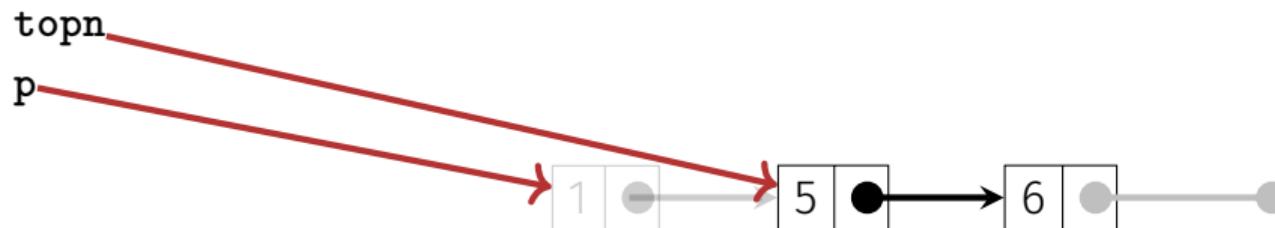

Dereferencing „dangling pointers”

- Pointer to released objects: **dangling pointers**
- Releasing an object more than once using `delete` is a similar severe error

# Stack Continued:

pop()

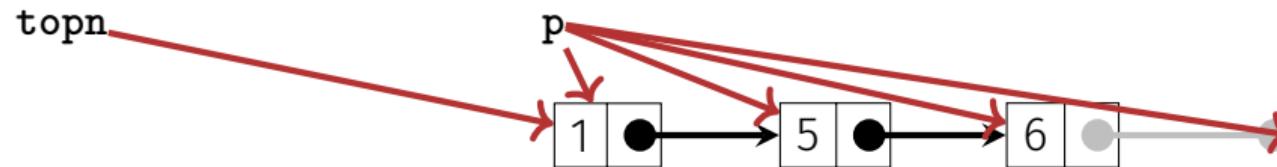

```
void stack::pop(){
    assert (!empty());
    llnode* p = topn;
    topn = topn->next;
    delete p;
}
reminder: shortcut for (*topn).next
```

# Print the Stack

print()

```
void stack::print (std::ostream& out) const {  
    for(const llnode* p = topn; p != nullptr; p = p->next)  
        out << p->value << " "; // 1 5 6  
}
```

# Output Stack:

operator<<

```
class stack {  
public:  
    void push (int value);  
    void pop();  
    void print (std::ostream& o) const;  
    ...  
private:  
    llnode* topn;  
};  
  
// POST: s is written to o  
std::ostream& operator<< (std::ostream& o, const stack& s){  
    s.print (o);  
    return o;  
}
```

## empty(), top()

```
bool stack::empty() const {
    return top == nullptr;
}
```

```
int stack::top() const {
    assert(!empty());
    return topn->value;
}
```

# Empty Stack

```
class stack{
public:
    stack() : topn (nullptr) {} // default constructor

    void push(int value);
    void pop();
    void print(std::ostream& out) const;
    int top() const;
    bool empty() const;

private:
    llnode* topn;
}
```

# Zombie Elements

```
{  
    stack s1; // local variable  
    s1.push (1);  
    s1.push (3);  
    s1.push (2);  
    std::cout << s1 << "\n"; // 2 3 1  
}  
// s1 has died (become invalid)...
```

- ...but the three elements of the stack `s1` continue to live (memory leak)!
- They should be released together with `s1`.

# The Destructor

- The Destructor of class  $T$  is the unique member function with declaration  
 $\sim T( );$
- is automatically called when the memory duration of a class object ends – i.e. when **delete** is called on an object of type  $T^*$  or when the enclosing scope of an object of type  $T$  ends.
- If no destructor is declared, it is automatically generated and calls the destructors for the member variables (pointers `topn`, no effect – reason for zombie elements)

# Using a Destructor, it Works

```
// POST: the dynamic memory of *this is deleted
stack::~stack(){
    while (topn != nullptr){
        llnode* t = topn;
        topn = t->next;
        delete t;
    }
}
```

- automatically deletes all stack elements when the stack is being released
- Now our stack class seems to follow the guideline “dynamic memory” (?)

# Stack Done?

Obviously not...

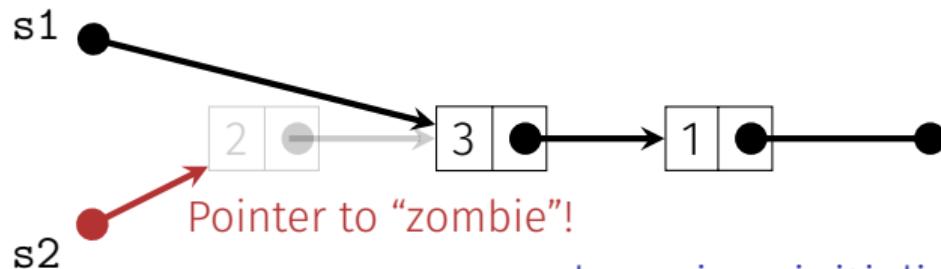

```
stack s1;
s1.push (1);
s1.push (3);
s1.push (2);
std::cout << s1 << "\n"; // 2 3 1
```

```
stack s2 = s1;
std::cout << s2 << "\n"; // 2 3 1
```

```
s1.pop ();
std::cout << s1 << "\n"; // 3 1
```

```
s2.pop (); // Oops, crash!
```

# What has gone wrong?

member-wise initialization: copies the  
topn pointer only.

```
...
stack s2 = s1; ←
std::cout << s2 << "\n"; // 2 3 1
```

```
s1.pop ();
std::cout << s1 << "\n"; // 3 1
```

```
s2.pop (); // Oops, crash!
```

# The actual problem

Already this goes wrong:

```
{  
    stack s1;  
    s1.push(1);  
    stack s2 = s1;  
}
```

When leaving the scope, both stacks are deconstructed. But both stacks try to delete the same data, because both stacks have **access to the same pointer**.

# Possible solutions

Smart-Pointers (we will not go into details here):

- Count the number of pointers referring to the same objects and delete only when that number goes down to 0 `std::shared_pointer`
- Make sure that not more than one pointer can point to an object:  
`std::unique_pointer`.

or:

- We make a real copy of all data – as discussed below.

# We make a real copy

...

```
stack s2 = s1;  
std::cout << s2 << "\n"; // 2 3 1
```

```
s1.pop ();  
std::cout << s1 << "\n"; // 3 1
```

```
s2.pop (); // ok
```

# The Copy Constructor

- The copy constructor of a class  $T$  is the unique constructor with declaration

$$T(\text{ const } T\& x);$$

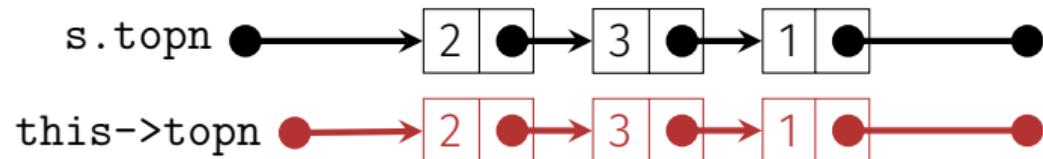

- is automatically called when values of type  $T$  are initialized with values of type  $T$

$$\begin{aligned} T \ x \ = \ t; & \quad (\text{t of type } T) \\ T \ x \ (t); & \end{aligned}$$

- If there is no copy-constructor declared then it is generated automatically (and initializes member-wise – reason for the problem above)

# It works with a Copy Constructor

```
// POST: *this is initialized with a copy of s
stack::stack (const stack& s) : topn (nullptr) {
    if (s.topn == nullptr) return;
    topn = new llnode(s.topn->value, nullptr);
    llnode* prev = topn;
    for(llnode* n = s.topn->next; n != nullptr; n = n->next){
        llnode* copy = new llnode(n->value, nullptr);
        prev->next = copy;
        prev = copy;
    }
}
```

prev

## Aside: copy recursively

```
llnode* copy (node* that){  
    if (that == nullptr) return nullptr;  
    return new llnode(that->value, copy(that->next));  
}
```

Elegant, isn't it? Why did we not do it like this?

Reason: linked lists can become very long. `copy` could then lead to stack overflow<sup>7</sup>. Stack memory is usually smaller than heap memory.

---

<sup>7</sup>not an overflow of the stack that we are implementing but the call stack

# Initialization ≠ Assignment!

```
stack s1;
s1.push (1);
s1.push (3);
s1.push (2);
std::cout << s1 << "\n"; // 2 3 1

stack s2;
s2 = s1; // Zuweisung

s1.pop ();
std::cout << s1 << "\n"; // 3 1
s2.pop (); // Oops, Crash!
```

# The Assignment Operator

- Overloading **operator=** as a member function
- Like the copy-constructor without initializer, but additionally
  - Releasing memory for the “old” value
  - Check for self-assignment ( $s1=s1$ ) that should not have an effect
- If there is no assignment operator declared it is automatically generated (and assigns member-wise – reason for the problem above)

# It works with an Assignment Operator!

```
// POST: *this (left operand) becomes a
//           copy of s (right operand)
stack& stack::operator= (const stack& s){
    if (topn != s.topn){ // no self-assignment
        stack copy = s; // Copy Construction
        std::swap(topn, copy.topn); // now copy has the garbage!
    } // copy is cleaned up -> deconstruction
    return *this; // return as L-Value (convention)
}
```

Cooool trick! 😊

# Done

```
class stack{
public:
    stack(); // constructor
    ~stack(); // destructor
    stack(const stack& s); // copy constructor
    stack& operator=(const stack& s); // assignment operator

    void push(int value);
    void pop();
    int top() const;
    bool empty() const;
    void print(std::ostream& out) const;
private:
    llnode* topn;
}
```

# Dynamic Datatype

- Type that manages dynamic memory (e.g. our class for a stack)
  - Minimal Functionality:
    - Constructors
    - Destructor
    - Copy Constructor
    - Assignment Operator
- } **Rule of Three:** if a class defines at least one of them, it must define all three

# Trees

Trees are

- Generalized lists: nodes can have more than one successor
- Special graphs: graphs consist of nodes and edges. A tree is a fully connected, directed, acyclic graph.

# Trees

Use

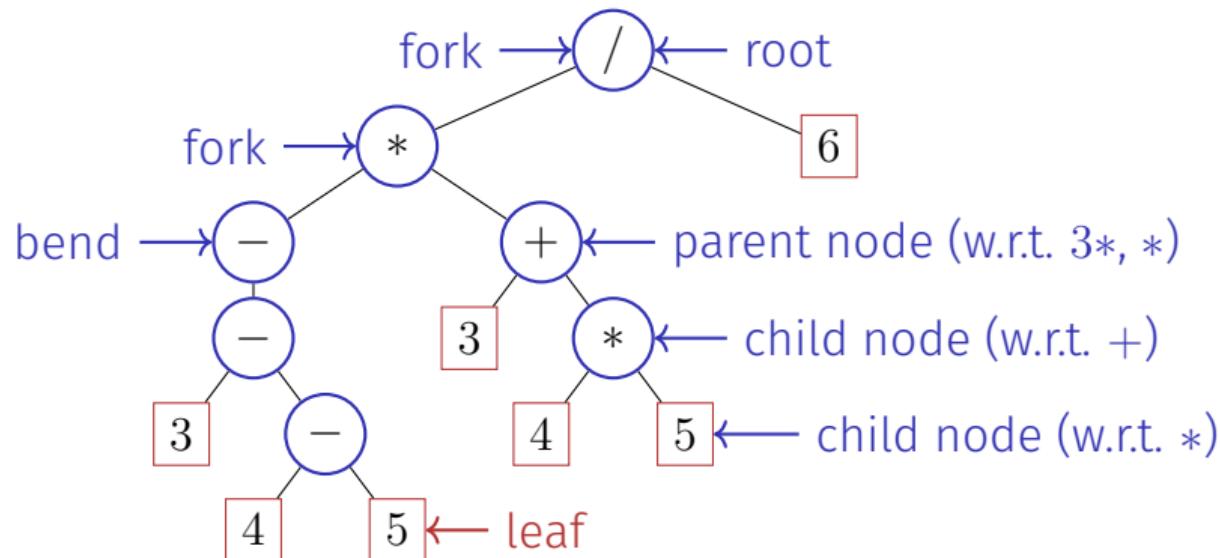

- Decision trees: hierachic representation of decision rules
- Code trees: representation of a code, e.g. morse alphabet, huffman code
- Search trees: allow efficient searching for an element by value
- **syntax trees: parsing and traversing of expressions, e.g. in a compiler**

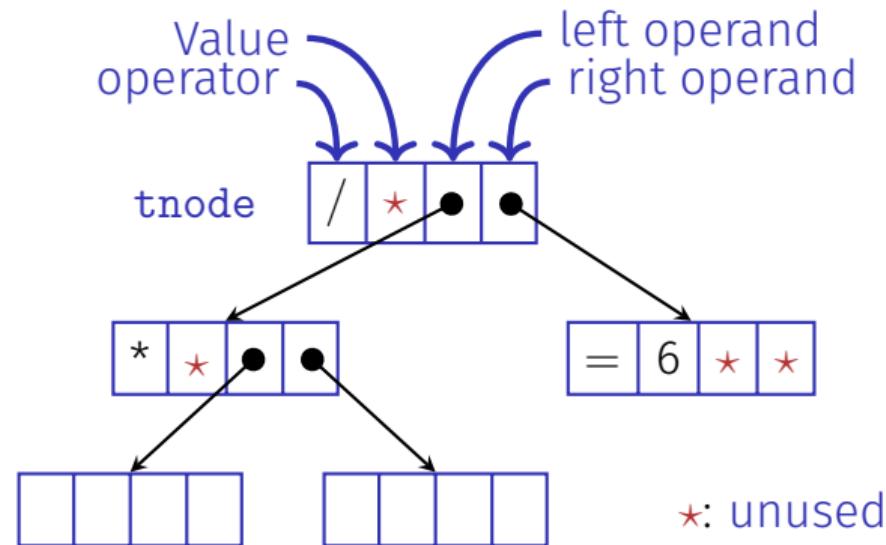

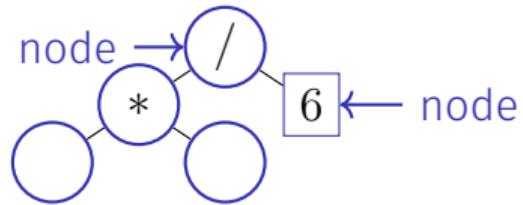

Trees are treated in more detail in other courses (Datastructures and Algorithms (CSE), Algorithms and Complexity (Math Bachelor))

# (Expression) Trees

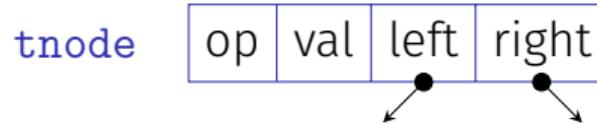

$$-(3-(4-5))*(3+4*5)/6$$

# Nodes: Forks, Bends or Leaves

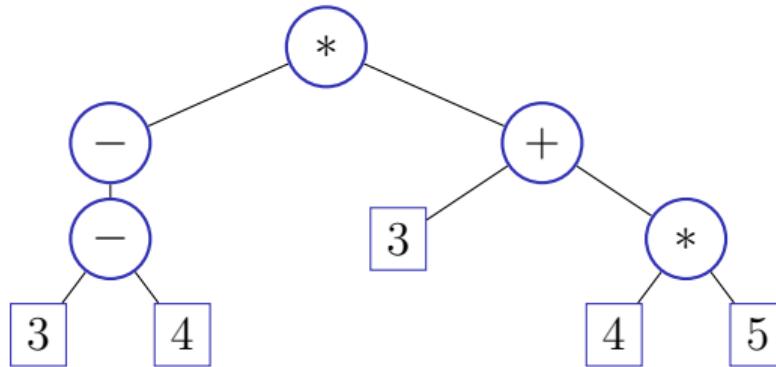

# Nodes (struct tnode)

```
struct tnode {  
    char op; // leaf node: op is '='  
              // internal node: op is '+', '-', '*' or '/'  
    double val;  
    tnode* left; // == nullptr for unary minus  
    tnode* right;  
  
    tnode(char o, double v, tnode* l, tnode* r)  
        : op(o), val(v), left(l), right(r) {}  
};
```

# Size = Count Nodes in Subtrees

- Size of a leave: 1
- Size of other nodes: 1 + sum of child nodes' size
- E.g. size of the "+"-node is 5

# Count Nodes in Subtrees

```
// POST: returns the size (number of nodes) of
//       the subtree with root n
int size (const tnode* n) {
    if (n){ // shortcut for n != nullptr
        return size(n->left) + size(n->right) + 1;
    }
    return 0;
}
```

# Evaluate Subtrees

```
// POST: evaluates the subtree with root n
double eval(const tnode* n){
    assert(n);
    if (n->op == '=') return n->val; ← leaf...
    double l = 0;                                ...or fork:
    if (n->left) l = eval(n->left); ← op unary, or left branch
    double r = eval(n->right); ← right branch
    switch(n->op){
        case '+': return l+r;
        case '-': return l-r;
        case '*': return l*r;
        case '/': return l/r;
        default: return 0;
    }
}
```

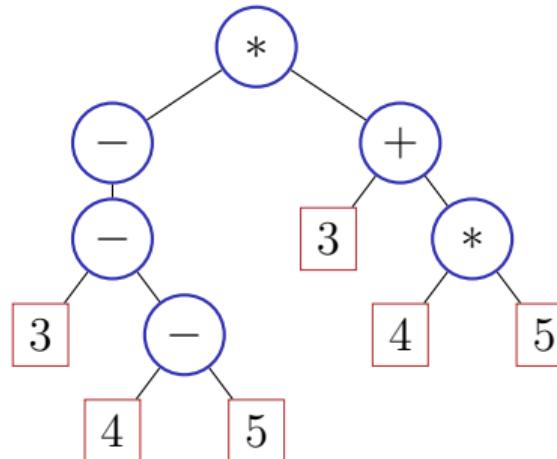

# Cloning Subtrees

```
// POST: a copy of the subtree with root n is made
//       and a pointer to its root node is returned
tnode* copy (const tnode* n) {
    if (n == nullptr)
        return nullptr;
    return new tnode (n->op, n->val, copy(n->left), copy(n->right));
}
```

# Felling Subtrees

```
// POST: all nodes in the subtree with root n are deleted
void clear(tnode* n) {
    if(n){
        clear(n->left);
        clear(n->right);
        delete n;
    }
}
```

# Using Expression Subtrees

```
// Construct a tree for 1 - (-(3 + 7))
tnode* n1 = new tnode('=', 3, nullptr, nullptr);
tnode* n2 = new tnode('=', 7, nullptr, nullptr);
tnode* n3 = new tnode('+', 0, n1, n2);
tnode* n4 = new tnode('-', 0, nullptr, n3);
tnode* n5 = new tnode('=', 1, nullptr, nullptr);
tnode* root = new tnode('-', 0, n5, n4);

// Evaluate the overall tree
std::cout << "1 - (-(3 + 7)) = " << eval(root) << '\n';

// Evaluate a subtree
std::cout << "3 + 7 = " << eval(n3) << '\n';

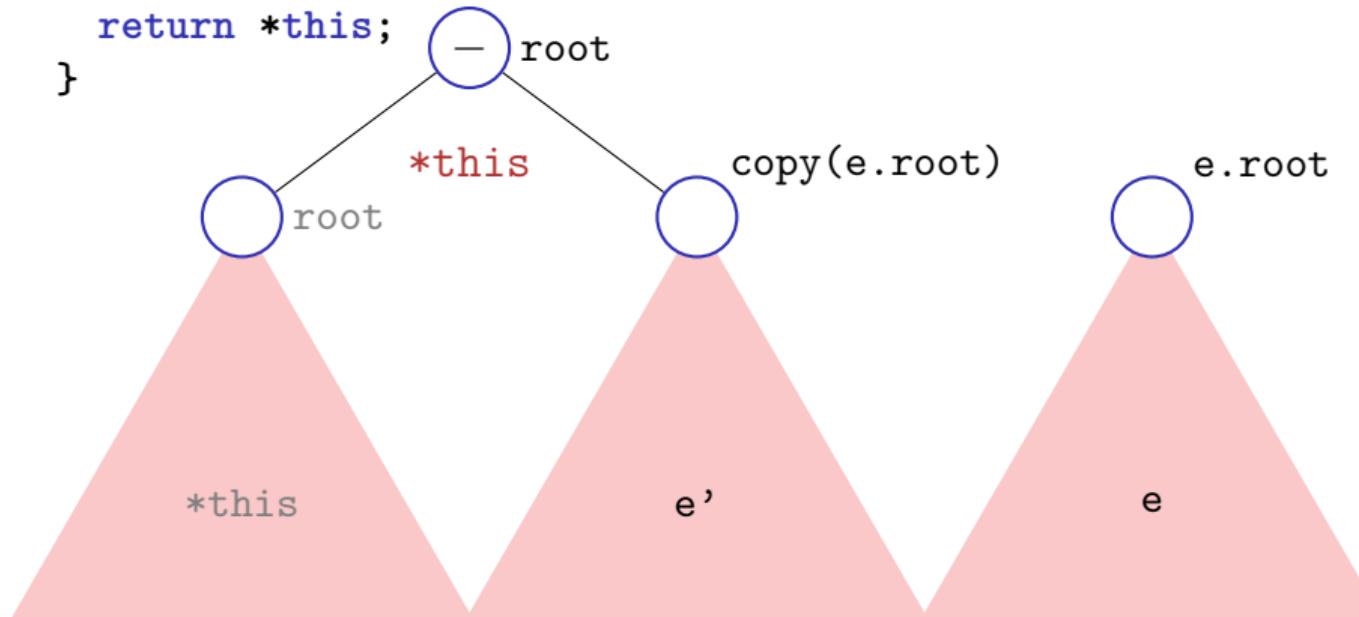

clear(root); // free memory
```

# Planting Trees

```
class texpression {           creates a tree with  
public:                      one leaf  
    texpression (double d) ←  
        : root (new tnode ('=', d, 0, 0)) {}  
    ...  
private:  
    tnode* root;  
};
```

# Letting Trees Grow

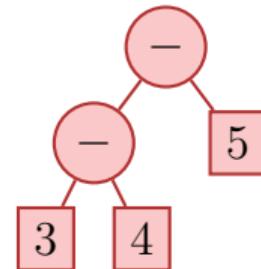

```
texpression& texpression::operator== (const texpression& e)
{
    assert (e.root);
    root = new tnode ('-', 0, root, copy(e.root));
    return *this;
}
```

# Raising Trees

```
texpression operator- (const texpression& l,  
                      const texpression& r){  
    texpression result = l;  
    return result -= r;  
}
```

```
texpression a = 3;  
texpression b = 4;  
texpression c = 5;  
texpression d = a-b-c;
```

## Rule of three: Clone, reproduce and cut trees

```
texpression::~texpression(){
    clear(root);
}

texpression::texpression (const texpression& e)
: root(copy(e.root)) { }

texpression& texpression::operator=(const texpression& e){
    if (root != e.root){
        texpression cp = e;
        std::swap(cp.root, root);
    }
    return *this;
}
```

# Concluded

```
class texpression{
public:
    texpression (double d); // constructor
    ~texpression(); // destructor
    texpression (const texpression& e); // copy constructor
    texpression& operator=(const texpression& e); // assignment op
    texpression operator-();
    texpression& operator==(const texpression& e);
    texpression& operator+=(const texpression& e);
    texpression& operator*=(const texpression& e);
    texpression& operator/=(const texpression& e);
    double evaluate();
private:
    tnode* root;
};
```

# From values to trees!

```
using number_type = texpression ;  
  
// term = factor { "*" factor | "/" factor }  
number_type term (std::istream& is){  
    number_type value = factor (is);  
    while (true) {  
        if (consume (is, '*'))  
            value *= factor (is);  
        else if (consume (is, '/'))  
            value /= factor (is);  
        else  
            return value;  
    }  
}
```

double\_calculator.cpp  
(expression value)  
→  
texpression\_calculator.cpp  
(expression tree)

# Concluding Remark

- In this lecture, we have intentionally refrained from implementing member functions in the node classes of the list or tree.<sup>8</sup>
- When there is inheritance and polymorphism used, the implementation of the functionality such as evaluate, print, clear (etc..) is better implemented in member functions.
- In any case it is not a good idea to implement the memory management of the composite data structure list or tree within the nodes.

---

<sup>8</sup>Parts of the implementations are even simpler (because the case `n==nullptr` can be caught more easily
