

Problem

21. Dynamic Datatypes and Memory Management

Last week: dynamic data type

Have allocated dynamic memory, but not released it again. In particular: no functions to remove elements from `llvec`.

Today: correct memory management!

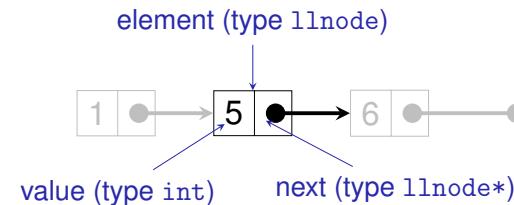

695

696

Goal: class stack with memory management

```
class stack{
public:
    // post: Push an element onto the stack
    void push(int value);
    // pre: non-empty stack
    // post: Delete top most element from the stack
    void pop();
    // pre: non-empty stack
    // post: return value of top most element
    int top() const;
    // post: return if stack is empty
    bool empty() const;
    // post: print out the stack
    void print(std::ostream& out) const;
    ...
}
```

Recall the Linked List

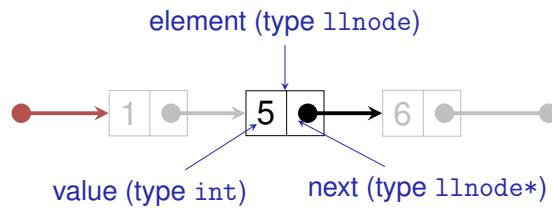

```
struct llnode {
    int value;
    llnode* next;
    // constructor
    llnode (int v, llnode* n) : value (v), next (n) {}
};
```

697

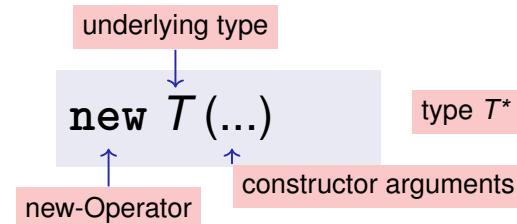

698

Stack = Pointer to the Top Element

```
class stack {  
public:  
    void push (int value);  
    ...  
private:  
    llnode* topn;  
};
```

Recall the new Expression

- **Effect:** new object of type T is allocated in memory ...
- ... and initialized by means of the matching constructor.
- **Value:** address of the new object

The new Expression

push(4)

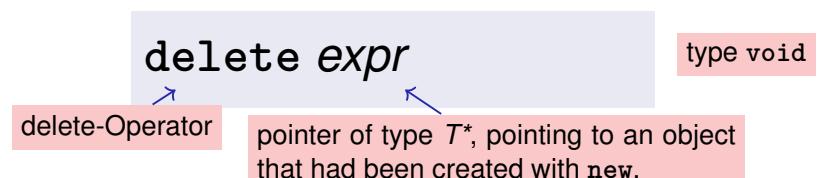

- **Effect:** new object of type T is allocated in memory ...
- ... and initialized by means of the matching constructor
- **Value:** address of the new object

```
void stack::push(int value){  
    topn = new llnode (value, topn);  
}  
  
topn
```

The diagram shows the state of the stack after a call to `push(4)`. The list now contains nodes with values 4, 1, 5, and 6. A red arrow points to the new node (4), which is highlighted with a red border. The sequence of pointers is 4 → 1 → 5 → 6 → null.

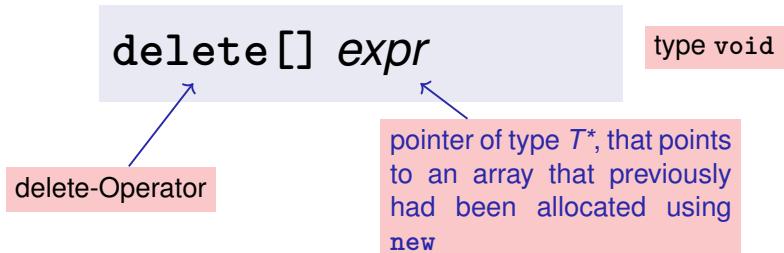

The delete Expression

Objects generated with `new` have *dynamic storage duration*: they “live” until they are explicitly *deleted*

- **Effect:** object is *deconstructed* (explanation below)
... and *memory is released*.

delete for Arrays

- **Effect:** array is deleted and memory is released

Who is born must die...

Guideline “Dynamic Memory”

For each `new` there is a matching `delete!`

Non-compliance leads to memory leaks

- old objects that occupy memory...
- ... until it is full (**heap overflow**)

703

704

Careful with new and delete!

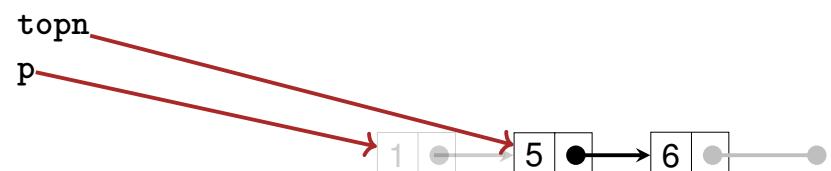

```
rational* t = new rational;           ← memory for t is allocated
rational* s = t;                     ← other pointers may point to the same object
delete s;                           ← ... and used for releasing the object
int nominator = (*t).denominator(); ← error: memory released!
                                         ↑
                                         Dereferencing of „dangling pointers“
```

- Pointer to released objects: *dangling pointers*
- Releasing an object more than once using `delete` is a similar severe error

Stack Continued:

```
void stack::pop(){
    assert (!empty());
    llnode* p = topn;
    topn = topn->next;
    delete p;
}
```

reminder: shortcut for `(*topn).next`

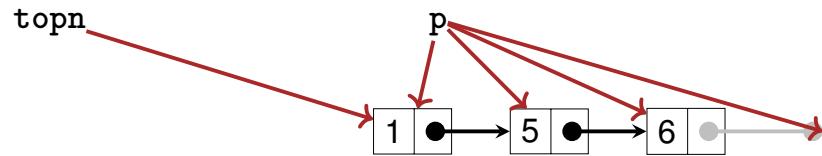

705

706

Print the Stack

```
void stack::print (std::ostream& out) const {
    for(const llnode* p = topn; p != nullptr; p = p->next)
        out << p->value << " "; // 1 5 6
}
```

print()

Output Stack:

operator<<

```
class stack {
public:
    void push (int value);
    void pop();
    void print (std::ostream& o) const;
    ...
private:
    llnode* topn;
};

// POST: s is written to o
std::ostream& operator<< (std::ostream& o, const stack& s){
    s.print (o);
    return o;
}
```

707

708

empty(), top()

```
bool stack::empty() const {
    return top == nullptr;
}

int stack::top() const {
    assert(!empty());
    return topn->value;
}
```

Empty Stack

```
class stack{
public:
    stack() : topn (nullptr) {} // default constructor

    void push(int value);
    void pop();
    void print(std::ostream& out) const;
    int top() const;
    bool empty() const;
private:
    llnode* topn;
}
```

709

710

Zombie Elements

```
{  
    stack s1; // local variable  
    s1.push (1);  
    s1.push (3);  
    s1.push (2);  
    std::cout << s1 << "\n"; // 2 3 1  
}  
// s1 has died (become invalid)...
```

- ...but the three elements of the stack s1 continue to live (memory leak)!
- They should be released together with s1.

The Destructor

- The Destructor of class *T* is the unique member function with declaration
 $\sim T();$
- is automatically called when the memory duration of a class object ends – i.e. when `delete` is called on an object of type *T** or when the enclosing scope of an object of type *T* ends.
- If no destructor is declared, it is automatically generated and calls the destructors for the member variables (pointers *topn*, no effect – reason for zombie elements)

711

712

Using a Destructor, it Works

```
// POST: the dynamic memory of *this is deleted  
stack::~stack(){  
    while (topn != nullptr){  
        llnode* t = topn;  
        topn = t->next;  
        delete t;  
    }  
}
```

- automatically deletes all stack elements when the stack is being released
- Now our stack class seems to follow the guideline “dynamic memory” (?)

Stack Done?

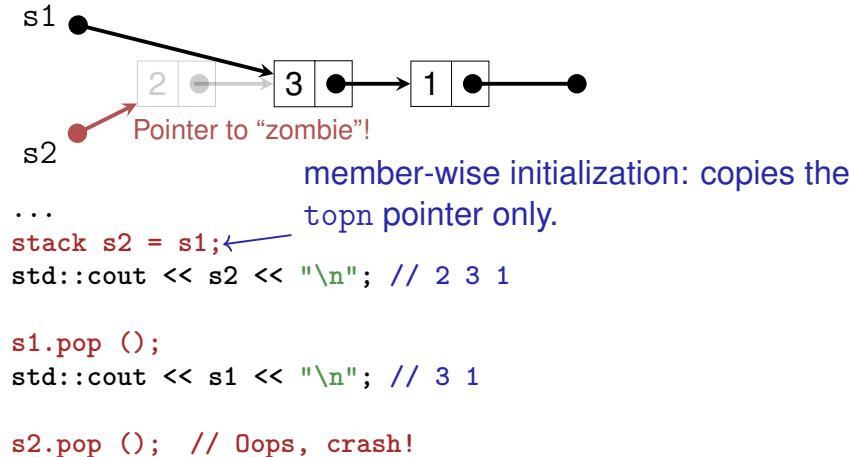

```
stack s1;  
s1.push (1);  
s1.push (3);  
s1.push (2);  
std::cout << s1 << "\n"; // 2 3 1  
  
stack s2 = s1;  
std::cout << s2 << "\n"; // 2 3 1  
  
s1.pop ();  
std::cout << s1 << "\n"; // 3 1  
  
s2.pop (); // Oops, crash!
```

713

Obviously not...

714

What has gone wrong?

The actual problem

Already this goes wrong:

```
{  
    stack s1;  
    s1.push(1);  
    stack s2 = s1;  
}
```

When leaving the scope, both stacks are deconstructed. But both stacks try to delete the same data, because both stacks have *access to the same pointer*.

Possible solutions

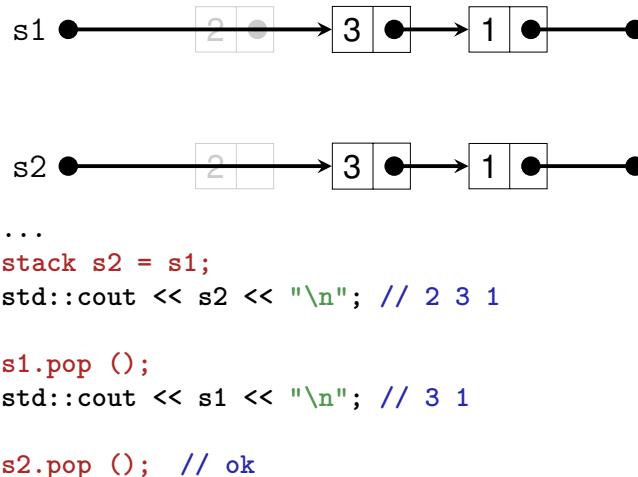

Smart-Pointers (we will not go into details here):

- Count the number of pointers referring to the same objects and delete only when that number goes down to 0
`std::shared_pointer`
- Make sure that not more than one pointer can point to an object:
`std::unique_pointer`.

or:

- We make a real copy of all data – as discussed below.

We make a real copy

The Copy Constructor

- The copy constructor of a class T is the unique constructor with declaration

```
 $T(\text{const } T\& x);$ 
```

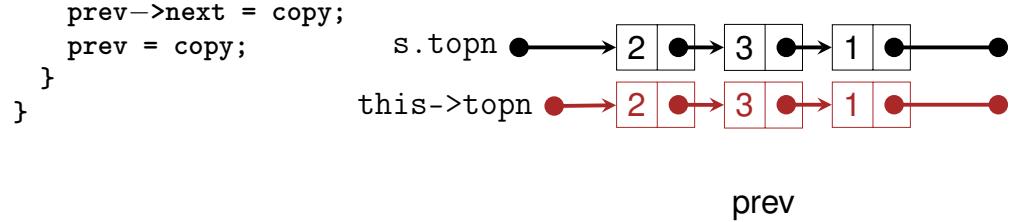

- is automatically called when values of type T are initialized with values of type T

```
 $T x = t; \quad (t \text{ of type } T)$   
 $T x(t);$ 
```

- If there is no copy-constructor declared then it is generated automatically (and initializes member-wise – reason for the problem above)

It works with a Copy Constructor

```
// POST: *this is initialized with a copy of s
stack::stack ( $\text{const stack\&} s$ ) : topn (nullptr) {
    if (s.topn == nullptr) return;
    topn = new llnode(s.topn->value, nullptr);
    llnode* prev = topn;
    for (llnode* n = s.topn->next; n != nullptr; n = n->next) {
        llnode* copy = new llnode(n->value, nullptr);
        prev->next = copy;
        prev = copy;
    }
}
```

Aside: copy recursively

```
llnode* copy (node* that){
    if (that == nullptr) return nullptr;
    return new llnode(that->value, copy(that->next));
}
```

Elegant, isn't it? Why did we not do it like this?

Reason: linked lists can become very long. `copy` could then lead to stack overflow⁷. Stack memory is usually smaller than heap memory.

Initialization \neq Assignment!

```
stack s1;
s1.push (1);
s1.push (3);
s1.push (2);
std::cout << s1 << "\n"; // 2 3 1

stack s2;
s2 = s1; // Zuweisung

s1.pop ();
std::cout << s1 << "\n"; // 3 1
s2.pop (); // Oops, Crash!
```

⁷not an overflow of the stack that we are implementing but the call stack

The Assignment Operator

- Overloading `operator=` as a member function
- Like the copy-constructor without initializer, but additionally
 - Releasing memory for the “old” value
 - Check for self-assignment ($s_1 = s_1$) that should not have an effect
- If there is no assignment operator declared it is automatically generated (and assigns member-wise – reason for the problem above)

It works with an Assignment Operator!

```
// POST: *this (left operand) becomes a
//           copy of s (right operand)
stack& stack::operator= (const stack& s){
    if (topn != s.topn){ // no self-assignment
        stack copy = s; // Copy Construction
        std::swap(topn, copy.topn); // now copy has the garbage
    } // copy is cleaned up -> deconstruction
    return *this; // return as L-Value (convention)
}
```

Cooool trick! 😊

723

724

Done

```
class stack{
public:
    stack(); // constructor
    ~stack(); // destructor
    stack(const stack& s); // copy constructor
    stack& operator=(const stack& s); // assignment operator

    void push(int value);
    void pop();
    int top() const;
    bool empty() const;
    void print(std::ostream& out) const;
private:
    llnode* topn;
}
```

Dynamic Datatype

- Type that manages dynamic memory (e.g. our class for a stack)
- Minimal Functionality:

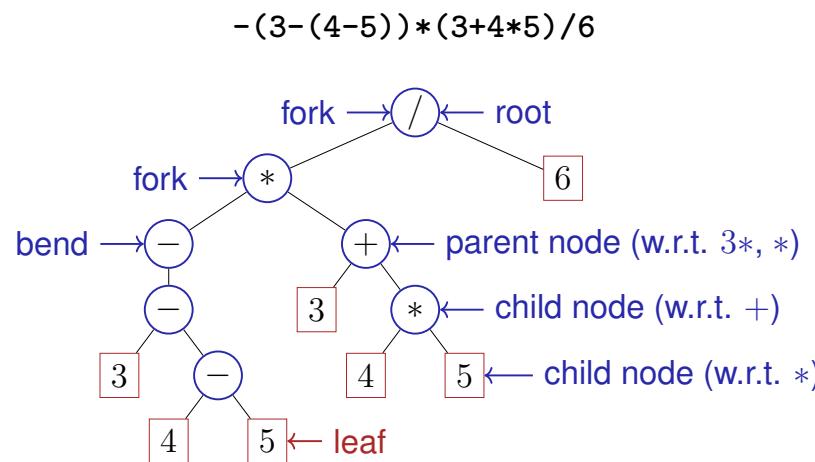

- Constructors
- Destructor
- Copy Constructor
- Assignment Operator

Rule of Three: if a class defines at least one of them, it must define all three

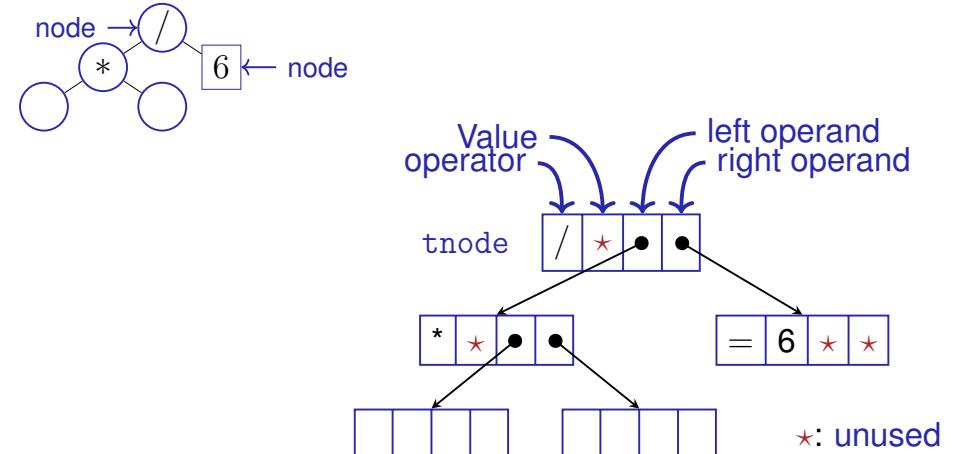

725

726

(Expression) Trees

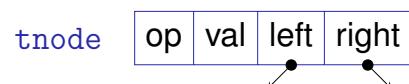

Nodes: Forks, Bends or Leaves

727

728

Nodes (struct tnode)

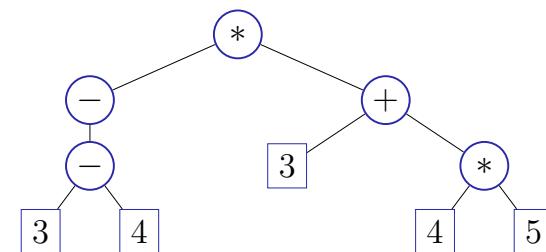

```
struct tnode {
    char op; // leaf node: op is '='
              // internal node: op is '+', '-',
              // '*', or '/'
    double val;
    tnode* left; // == nullptr for unary minus
    tnode* right;

    tnode(char o, double v, tnode* l, tnode* r)
        : op(o), val(v), left(l), right(r) {}

};
```

Size = Count Nodes in Subtrees

- Size of a leave: 1
- Size of other nodes: 1 + sum of child nodes' size
- E.g. size of the "+"-node is 5

729

730

Count Nodes in Subtrees

```
// POST: returns the size (number of nodes) of
//       the subtree with root n
int size (const tnode* n) {
    if (n){ // shortcut for n != nullptr
        return size(n->left) + size(n->right) + 1;
    }
    return 0;
}
```

```
// POST: a copy of the subtree with root n is made
//       and a pointer to its root node is returned
tnode* copy (const tnode* n) {
    if (n == nullptr)
        return nullptr;
    return new tnode (n->op, n->val, copy(n->left), copy(n->right));
}
```

Evaluate Subtrees

```
// POST: evaluates the subtree with root n
double eval(const tnode* n){
    assert(n);
    if (n->op == '=') return n->val; ← leaf...
    double l = 0;                                ...or fork:
    if (n->left) l = eval(n->left); ← op unary, or left branch
    double r = eval(n->right); ← right branch
    switch(n->op){
        case '+': return l+r;
        case '-': return l-r;
        case '*': return l*r;
        case '/': return l/r;
        default: return 0;
    }
}
```

731

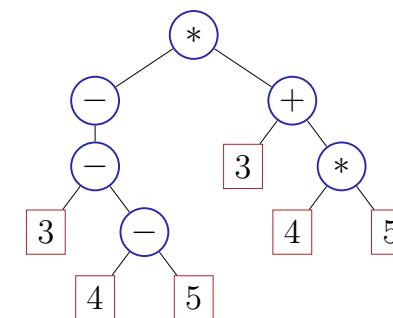

732

Cloning Subtrees

```
// POST: a copy of the subtree with root n is made
//       and a pointer to its root node is returned
tnode* copy (const tnode* n) {
    if (n == nullptr)
        return nullptr;
    return new tnode (n->op, n->val, copy(n->left), copy(n->right));
}
```

Felling Subtrees

```
// POST: all nodes in the subtree with root n are deleted
void clear(tnode* n) {
    if(n){
        clear(n->left);
        clear(n->right);
        delete n;
    }
}
```

733

734

Using Expression Subtrees

```
// Construct a tree for 1 - (-(3 + 7))
tnode* n1 = new tnode('=', 3, nullptr, nullptr);
tnode* n2 = new tnode('=', 7, nullptr, nullptr);
tnode* n3 = new tnode('+', 0, n1, n2);
tnode* n4 = new tnode('-', 0, nullptr, n3);
tnode* n5 = new tnode('=', 1, nullptr, nullptr);
tnode* root = new tnode('-', 0, n5, n4);

// Evaluate the overall tree
std::cout << "1 - (-(3 + 7)) = " << eval(root) << '\n';

// Evaluate a subtree
std::cout << "3 + 7 = " << eval(n3) << '\n';

clear(root); // free memory
```

Planting Trees

```
class texpression {
public:
    texpression (double d) creates a tree with one leaf
        : root (new tnode ('=', d, 0, 0)) {}

    ...
private:
    tnode* root;
};
```

735

736

Letting Trees Grow

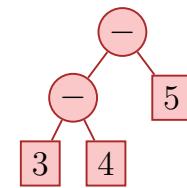

```
texpression& texpression::operator-= (const texpression& e)
{
    assert (e.root);
    root = new tnode ('-', 0, root, copy(e.root));
    return *this;
}
```

Raising Trees

```
texpression operator- (const texpression& l,
                      const texpression& r){
    texpression result = l;
    result -= r;
}
```

```
texpression a = 3;
texpression b = 4;
texpression c = 5;
texpression d = a-b-c;
```

737

738

Rule of three: Clone, reproduce and cut trees

```
texpression::~texpression(){
    clear(root);
}

texpression::texpression (const texpression& e)
    : root(copy(e.root)) { }

texpression::texpression& operator=(const texpression& e){
    if (root != e.root){
        texpression cp = e;
        std::swap(cp.root, root);
    }
    return *this;
}
```

Concluded

```
class texpression{
public:
    texpression (double d); // constructor
    ~texpression(); // destructor
    texpression (const texpression& e); // copy constructor
    texpression& operator=(const texpression& e); // assignment op
    texpression operator-();
    texpression& operator+=(const texpression& e);
    texpression& operator*=(const texpression& e);
    texpression& operator/=(const texpression& e);
    double evaluate();
private:
    tnode* root;
};
```

739

740

From values to trees!

```
using number_type = texpression ;

// term = factor { "*" factor | "/" factor }
number_type term (std::istream& is){
    number_type value = factor (is);
    while (true) {
        if (consume (is, '*'))
            value *= factor (is);
        else if (consume (is, '/'))
            value /= factor (is);
    else
        return value;
    }
}
```

double_calculator.cpp
(expression value)
→
texpression_calculator.cpp
(expression tree)

Concluding Remark

- In this lecture, we have intentionally refrained from implementing member functions in the node classes of the list or tree.⁸
- When there is inheritance and polymorphism used, the implementation of the functionality such as evaluate, print, clear (etc..) is better implemented in member functions.
- In any case it is not a good idea to implement the memory management of the composite data structure list or tree within the nodes.

⁸Parts of the implementations are even simpler (because the case n==nullptr can be caught more easily

741

742
