

13. Arrays II

Strings, Lindenmayer Systems, Multidimensional Arrays, Vectors of Vectors, Shortest Paths, Arrays and Vectors as Function Arguments

Texts

- can be represented with the type `std::string` from the standard library.

```
std::string text = "bool";
```

defines a string with length 4

- A string is conceptually an array with base type `char`, plus additional functionality
- Requires `#include <string>`

Strings as Arrays

- can be represented with underlying type `char`

```
char text[] a = ...
```

- can be initialized via string literals

```
char text[] = "bool"
```

- this is equivalent to the following initialisation

```
char text[] = {'b','o','o','l','\0'}
```

- can only be defined with constant size

Strings: pimped `char`-Arrays

A `std::string...`

- knows its length

```
text.length()
```

returns its length as `int` (call of a member function; will be explained later)

- can be initialized with variable length

```
std::string text (n, 'a')
```

`text` is filled with `n` 'a's

- "understands" comparisons

```
if (text1 == text2) ...
```

true if `text1` and `text2` match

Lindenmayer-Systems (L-Systems)

Fractals made from Strings and Turtles

L-Systems have been invented by the Hungarian biologist Aristid Lindenmayer (1925 – 1989) to model the growth of plants.

Definition and Example

- Alphabet Σ
- Σ^* : all finite words over Σ
- Production $P : \Sigma \rightarrow \Sigma^*$
- Initial word $s_0 \in \Sigma^*$

	$\{F, +, -\}$
c	$P(c)$
F	F + F +
+	+
-	-
F	

Definition

The triple $\mathcal{L} = (\Sigma, P, s_0)$ is an L-System.

The Described Language

Words $w_0, w_1, w_2, \dots \in \Sigma^*$:

$$P(F) = F + F +$$

$$w_0 := s_0$$

$$w_0 := F$$

$$w_1 := P(w_0)$$

$$w_1 := F + F +$$

$$w_2 := P(w_1)$$

$$w_2 := F + F + + F + F + +$$

$P(F)P(+)P(F)P(+)$

⋮

⋮

Definition

$$P(c_1 c_2 \dots c_n) := P(c_1)P(c_2) \dots P(c_n)$$

Turtle-Graphics

Turtle with position and direction.

Turtle understands 3 commands:

F: one step forward ✓

trace

+ : turn by 90 degrees ✓

- : turn by -90 degrees ✓

Draw Words!

$$w_1 = F + F + \checkmark$$

lindenmayer.cpp:

Words $w_0, w_1, w_2, \dots, w_n \in \Sigma^*$:

```
...
#include "turtle.h"
...
std::cout << "Number of iterations =? ";
unsigned int n;
std::cin >> n;
```

std::string w = "F";

$w = w_0 = F$

```
for (unsigned int i = 0; i < n; ++i)
    w = next_word (w);
```

$w = w_i \rightarrow w = w_{i+1}$

draw_word (w);

draw $w = w_n$!

443

444

lindenmayer.cpp:

next_word

```
// POST: replaces all symbols in word according to their
//       production and returns the result
std::string next_word (std::string word) {
    std::string next;
    for (unsigned int k = 0; k < word.length(); ++k)
        next += production (word[k]);
    return next;
}

// POST: returns the production of c
std::string production (char c) {
    switch (c) {
    case 'F': return "F+F+";
    default: return std::string (1, c); // trivial production c -> c
    }
}
```

445

Main Program

lindenmayer.cpp:

draw_word

```
// POST: draws the turtle graphic interpretation of word
void draw_word (std::string word)
{
```

```
    for (unsigned int k = 0; k < word.length(); ++k)
```

jump to the case that corresponds to word [k].

```
        switch (word[k]) {
```

```
            case 'F':
```

```
                turtle::forward();
```

forward! (function from our turtle library)

```
                break;
```

skip the remaining cases

```
            case '+':
```

```
                turtle::left(90);
```

turn by 90 degrees! (function from our turtle library)

```
                break;
```

```
            case '-':
```

```
                turtle::right(90);
```

turn by -90 degrees (function from our turtle library)

}

444

- Additional symbols without graphical interpretation (`dragon.cpp`)
- Arbitrary angles (`snowflake.cpp`)
- Saving and restoring the turtle state → plants (`bush.cpp`)

447

Multidimensional Arrays

- are arrays of arrays
- can be used to store *tables*, *matrices*,

`int a[2][3]`

a contains two elements and each of them is an array of length 3 with base type `int`

449

448

Multidimensional Arrays

In memory: flat

in our head: matrix

		columns →		
		0	1	2
rows ↓	0	<code>a[0][0]</code>	<code>a[0][1]</code>	<code>a[0][2]</code>
	1	<code>a[1][0]</code>	<code>a[1][1]</code>	<code>a[1][2]</code>

450

Multidimensional Arrays

- are arrays of arrays of arrays

$T a[\text{expr}_1] \dots [\text{expr}_k]$

constant expressions

a has expr_1 elements and each of them is an array with expr_2 elements each of which is an array of expr_3 elements and ...

Multidimensional Arrays

Initialization

```
int a[][3] =  
{  
    {2, 4, 6}, {1, 3, 5}  
}
```

First dimension can be omitted

2	4	6	1	3	5
---	---	---	---	---	---

Vectors of Vectors

- How do we get multidimensional arrays with variable dimensions?
- Solution: vectors of vectors

Example: vector of length n of vectors with length m :

```
std::vector<std::vector<int>> a(n,  
    std::vector<int>(m));
```

Application: Shortest Paths

Factory hall ($n \times m$ square cells)

Application: shortest paths

Solution

This problem appears to be different

Find the *lengths* of the shortest paths to *all* possible targets.

This solves the original problem also: start in T; follow a path with decreasing lengths

This problem appears to be different

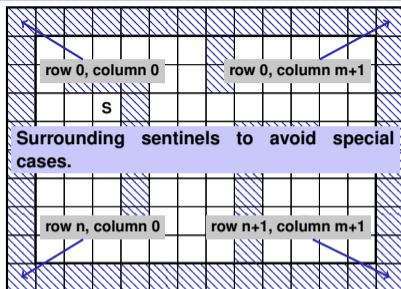

Find the *lengths* of the shortest paths to *all* possible targets.

Preparation: Input Format

Preparation: Sentinels

Preparation: Initial Marking

The Shortest Path Program

- Read in dimensions and provide a two dimensional array for the path lengths

```
#include<iostream>
#include<vector>

int main()
{
    // read floor dimensions
    int n; std::cin >> n; // number of rows
    int m; std::cin >> m; // number of columns

    // define a two-dimensional
    // array of dimensions
    // (n+2) x (m+2) to hold the floor plus extra walls around
    std::vector<std::vector<int>> floor (n+2, std::vector<int>(m+2));
```

Sentinel

The Shortest Path Program

- Input the assignment of the hall and initialize the lengths

```
int tr = 0;
int tc = 0;
for (int r=1; r<n+1; ++r)
    for (int c=1; c<m+1; ++c) {
        char entry = '-';
        std::cin >> entry;
        if (entry == 'S') floor[r][c] = 0;
        else if (entry == 'T') floor[tr = r][tc = c] = -1;
        else if (entry == 'X') floor[r][c] = -2;
        else if (entry == '-') floor[r][c] = -1;
    }
```

■ Add the surrounding walls

```
for (int r=0; r<n+2; ++r)
    floor[r][0] = floor[r][m+1] = -2;

for (int c=0; c<m+2; ++c)
    floor[0][c] = floor[n+1][c] = -2;
```

Step 2: all cells with path length 2

Main Loop

Find and mark all cells with path lengths $i = 1, 2, 3, \dots$

```
for (int i=1; ; ++i) {
    bool progress = false;
    for (int r=1; r<n+1; ++r)
        for (int c=1; c<m+1; ++c) {
            if (floor[r][c] != -1) continue;
            if (floor[r-1][c] == i-1 || floor[r+1][c] == i-1 ||
                floor[r][c-1] == i-1 || floor[r][c+1] == i-1) {
                floor[r][c] = i; // label cell with i
                progress = true;
            }
        }
    if (!progress) break;
}
```

The Shortest Paths Program

Mark the shortest path by walking backwards from target to start.

```
int r = tr; int c = tc;
while (floor[r][c] > 0) {
    const int d = floor[r][c] - 1;
    floor[r][c] = -3;
    if (floor[r-1][c] == d) --r;
    else if (floor[r+1][c] == d) ++r;
    else if (floor[r][c-1] == d) --c;
    else ++c; // (floor[r][c+1] == d)
}
```

	-3	-3	-3	-3	-3	-3		15	16	17	18	19										
	-3					9	-3		14	15	16	17	18									
	-3	-3	0			10	-3	-3	-3	-3	-3	-3	17									
	3	2	1			11	12	13						-3	18							
	4	3	2			10	11	12				20	-3	-3	19							
	5	4	3			9	10	11				21	-3	19	20							
	6	5	4			8	9	10				22	-3	20	21							
	7	6	5	6	7	8	9					23	22	21	22							

Output

```
for (int r=1; r<n+1; ++r) {
  for (int c=1; c<m+1; ++c)
    if (floor[r][c] == 0)
      std::cout << 'S';
    else if (r == tr && c == tc)
      std::cout << 'T';
    else if (floor[r][c] == -3)
      std::cout << 'o';
    else if (floor[r][c] == -2)
      std::cout << 'X';
    else
      std::cout << '-';
  std::cout << "\n";
}
```

```
ooooooX-----
oXXX-oX-----
ooSX-oooooooo-
---X---XXXo-
---X---X-oo-
---X---X-o--
---X---X-T--
-----X-----
```

The Shortest Paths Program

- Algorithm: *Breadth First Search*
- The program can become pretty slow because for each i all cells are traversed
- Improvement: for marking with i , traverse only the neighbours of the cells marked with $i - 1$.
- Improvement: stop once the goal has been reached

Arrays as Function Arguments

Arrays can also be passed as *reference* arguments to a function. (here: `const` because v is read-only)

```
void print_vector(const int (&v)[3]) {
  for (int i = 0; i<3 ; ++i) {
    std::cout << v[i] << " ";
  }
}
```

Arrays as Function Arguments

This also works for multidimensional arrays.

```
void print_matrix(const int (&m)[3][3]) {
    for (int i = 0; i<3 ; ++i) {
        print_vector (m[i]);
        std::cout << "\n";
    }
}
```

472

Vectors as Function Arguments

This also works for multidimensional vectors.

```
void print_matrix(const std::vector<std::vector<int> >& m) {
    for (int i = 0; i<m.size() ; ++i) {
        print_vector (m[i]);
        std::cout << "\n";
    }
}
```

474

Vectors as Function Arguments

Vectors can be passed *by value* or *by reference*

```
void print_vector(const std::vector<int>& v) {
    for (int i = 0; i<v.size() ; ++i) {
        std::cout << v[i] << " ";
    }
}
```

Here: *call by reference* is more efficient because the vector could be very long

473

14. Pointers, Algorithms, Iterators and Containers I

Pointers, Address operator, Dereference operator, Array-to-Pointer Conversion

475

Random Access is Useful

```
int a[] = ...; // large array
```

```
a[13] = ...;
```

```
a[77] = ...;
```

```
a[50] = ...;
```

Random Access is Useful

```
int a[] = ...; // large array
```

```
a[13] = ...;
```

```
a[77] = ...;
```

```
a[50] = ...;
```

compute $a + 13 \cdot s$

compute $a + 77 \cdot s$

compute $a + 50 \cdot s$

One **addition** and one **multiplication** per element access

Random Access is Often Unnecessary

```
int a[] = ...; // large array
```

```
for (int i = 0; i < n; ++i)
```

```
  a[i] = ...;
```

compute $a + 0 \cdot s$

compute $a + 1 \cdot s$

compute $a + 2 \cdot s$

...

- Access pattern is called **sequential access**
- Should only “cost” one **addition** per element access

Reading a book ... with random access

... with

Random Access

- open book on page 1
- close book
- open book on pages 2-3
- close book
- open book on pages 4-5
- close book
- ...

Sequential Access

- open book on page 1
- turn the page
- turn the page
- turn the page
- turn the page
- ...

Wanted: Pointers into Arrays

```
for (pointer p = begin of a;  
    p < end of a;  
    increment p memory width of int)  
    a[i] = ...;
```

We need to be able to use memory addresses directly!

- Queries: Begin/end of a
- Comparisons: $p < \dots$
- Arithmetic: increment p

References: Where is Anakin?

“Search for Vader, and Anakin find you will”

```
int anakin_skywalker = 9;  
int& darth_vader = anakin_skywalker;  
darth_vader = 22;  
  
// anakin_skywalker = 22
```

Pointers: Where is Anakin?

```
int anakin_skywalker = 9;  
int* here = &anakin_skywalker;  
std::cout << here; // Address  
*here = 22;  
  
// anakin_skywalker = 22
```

“Anakins address is
0x7fff6bdd1b54.”

Pointer Types

Value of a pointer to T is the address of an object of type T.

Beispiele

```
int* p; Variable p is pointer to an int.  
float* q; Variable q is pointer to a float.
```

```
int* p = ...;
```

Address Operator

The expression

L-value of type T

↓
& lval

provides, as R-value, a *pointer* of type T^* to an object at the address of *lval*

The operator `&` is called **Address-Operator**.

Address Operator

Example

```
int i = 5;  
int* ip = &i; // ip initialized  
           // with address of i.
```

Dereference Operator

The expression

R-value of type T*

↓
* rval

returns as L-value the *value* of the object at the address represented by *rval*.

The operator `*` is called **Dereference Operator**.

Dereference Operator

Beispiel

```
int i = 5;  
int* ip = &i; // ip initialized  
           // with address of i.  
int j = *ip; // j == 5
```

Do not point with a `double*` to an `int`!

Examples

```
int* i = ...; // at address i "lives" an int...
double* j = i; //...and at j lives a double: error!
```

Mnemonic Trick

The declaration

```
T* p;    p is of the type "pointer to T"
```

can be read as

```
T *p;    *p is of type T
```

Although this is legal, we do not write it like this!

Pointer Arithmetics: Pointer plus `int`

- `ptr`: Pointer to element `a[k]` of the array `a` with length `n`
- Value of `expr`: integer `i`, such that $0 \leq k + i \leq n$

ptr + expr

is a pointer to `a[k + i]`.

For $k + i = n$ we get a *past-the-end*-pointer that must not be dereferenced.

Pointer Arithmetics: Pointer minus `int`

- If `ptr` is a pointer to the element with index k in an array a with length n

- and the value of `expr` is an integer i , $0 \leq k - i \leq n$,

then the expression

`ptr - expr`

provides a pointer to an element of a with index $k - i$.

The Truth about Random Access

The expression

`a[i]`

is equivalent to

`*(a + i)`
↑
`a + i * s`

Conversion Array \Rightarrow Pointer

How do we get a pointer to the first element of an array?

- Static array of type $T[n]$ is convertible to T^*

Example

```
int a[5];  
int* begin = a; // begin points to a[0]
```

- Length information is lost (“arrays are primitive”)

Finally: Iteration over an Array of Pointers

Example

```
int a[5] = {3, 4, 6, 1, 2};  
for (int* p = a; p < a+5; ++p)  
    std::cout << *p << ' '; // 3 4 6 1 2
```

- `a+5` is a pointer behind the end of the array (past-the-end) **that must not be dereferenced.**
- The pointer comparison (`p < a+5`) refers to the order of the two addresses in memory.
